Sustainability Practices for Anhsin Bridge Construction of Ankeng MRT System in New Taipei City

ABSTRACT

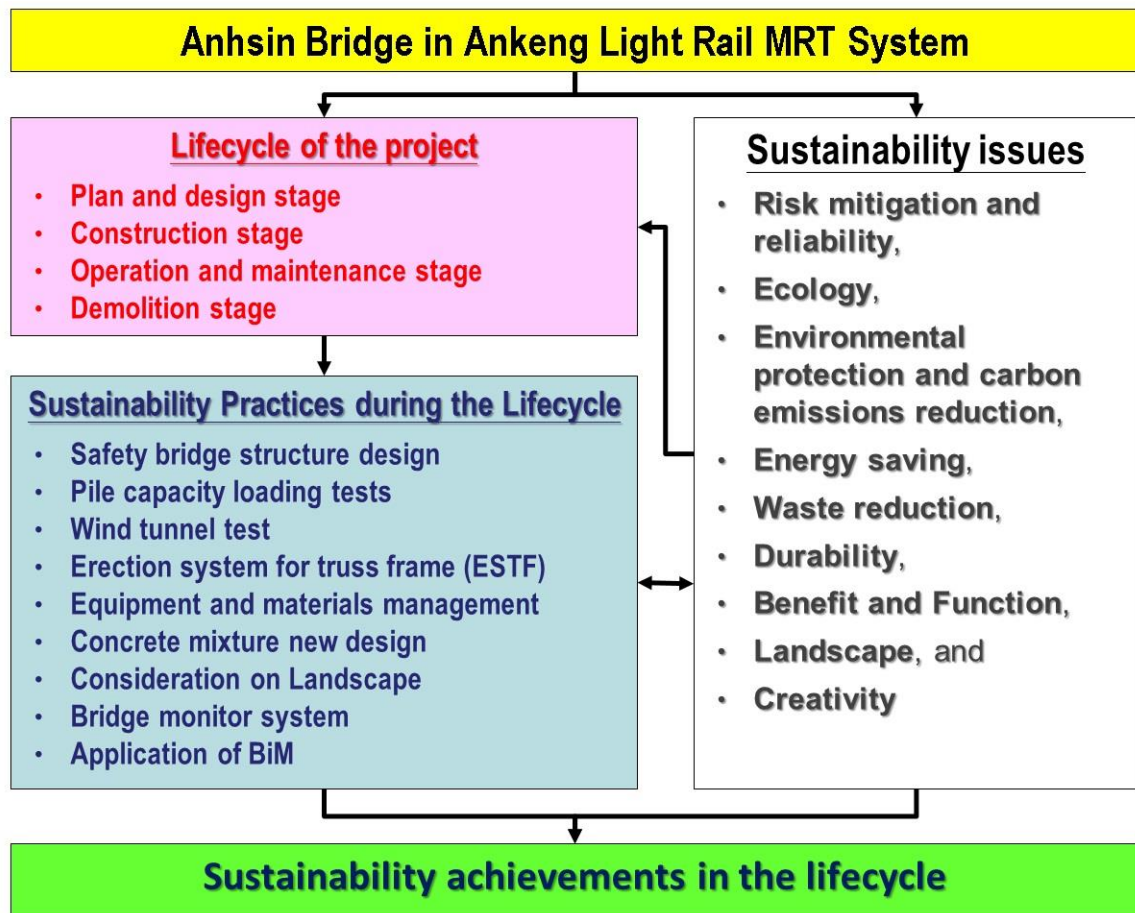

The Ankeng Light Rail Metro System (ALRMS) is a Design-Build (DB) based contract project, which is located in New Taipei City, Taiwan. The Anhsin Bridge (AB) is one of the major parts of ALRMS and serves as the most critical transportation route to connect two banks of the Hsindian River, Ankeng and Hsindian districts. For the sustainability consideration, the Contractor, New Asia Construction and Development Corporation (NA), of the ALRMS made some efforts by adopting the sustainable practices starting from the design stage of this project. These sustainable practices, including Risk mitigation and reliability, Ecology, Environmental protection and carbon emissions reduction, Energy saving, Waste reduction, Durability, Benefit and Function, Landscape, and Creativity, are being considered and discussed as key indicators of sustainability issues. In this paper, the authors would like to share the experiences on the significant achievement of sustainable practices. Furthermore, the development of the sustainability indicators and concept is introduced in this paper.

Keywords: Sustainability practices, Ankeng Light Rail Metro System, Anhsin bridge

1. Introduction

Sustainability indicators for the development of infrastructure projects were proposed in the past decades [1-3], with the key assessment indicators proposed for evaluating sustainability issues in engineering fields [4]. The corresponding author, Tai-Yi Liu, of this paper, proposed a reliable and practical sustainability assessment system for green civil infrastructure (SASGCI) in his doctoral dissertation in January 2020 [3]. It provided a new consideration for sustainability practices when

23 developing a new infrastructure project. In recent years, sustainability issues have been widely
 24 studied and discussed in all engineering fields as well as construction. It is also aware of taking
 25 sustainability considerations from the beginning, such as the plan and design stages of a new project.
 26 The primary purpose of conducting sustainability research is to prevent construction projects from
 27 depleting resources and causing harmful effects and impact on the environment and ecology during
 28 their lifecycles [4-5]. In this project, engineers discussed all sustainability practices for the AB
 29 construction to minimize the possible impact on the environment and human life during the lifecycle
 30 of the ALRMS [6]. The authors all involve this project and would like to share the references on
 31 developing sustainability research during this project. Fig. 1 shows the research framework in this
 32 paper.

33
34 **Figure 1:** The research framework.

1
2
3 35 **2. The concept for the sustainability indicators**
4

5 36 Efforts in sustainability draw attention and public support for infrastructures such as residential
6
7
8 37 houses, roads, highways, bridges, tunnels, water supply, sewers, electrical grids, and
9
10 38 telecommunications, just to name a few. Specifically, sustainable and green infrastructures are
11
12 39 being emphasized through designs and constructions that support long-term sustainability [7].
13
14
15 40 Sustainable and green civil infrastructure, including bridge, may contain the following criteria [8-
16
17
18 41 11]:

- 19
20 42 • Maintain safety management, risk mitigation, and reliability during the lifecycle.
- 21
22 43 • Minimize the CO₂ emission during the lifecycle, and harmful impacts on the environment
23
24 and ecology.
- 25 44 • Optimize the landscape for the project developed zone.
- 26
27 45 • Maximize the benefit/function of project development.
- 28
29 46 • Reduce the waste-producing and try possible recycle for the wastes during the lifecycle.
- 30
31 47 • Save the energy during the lifecycle.
- 32
33 48 • Extend the durability of the project.
- 34
35 49 • Preserve the local culture, and maintain the social conscience.
- 36
37 50 • Encourage creativity.
- 38
39 51 • Keep a reasonable cost during the lifecycle.
- 40
41 52

42
43
44 53 Liu performed the research for the evaluation of the civil infrastructures [3]. Some important
45
46
47 54 issues are taken into consideration as the “Key Indicators” of the **Sustainability Assessment System**
48
49
50 55 **for Green Civil Infrastructure** (SASGCI). It is the first level of the assessment system. Each
51
52
53 56 indicator should contain some related evaluation items as the second level of the assessment system.
54
55
56 57 For consideration of the entire lifecycle of a project, it is necessary to cover four stages, which include
57
58
59 58 design, construction, operation, and demolition, to be level three of the system [3].
60
61
62
63
64
65

1
2
3 59 Ten sustainability indicators for the bridge were proposed in Liu’s research, which are listed as

4
5 60 follows [3]:

- 6
7
8 61 • **Risk mitigation and reliability**
9
10 62 • **Ecology**
11
12 63 • **Environmental protection and carbon emissions reduction**
13
14
15 64 • **Energy saving**
16
17 65 • **Waste reduction**
18
19
20 66 • **Durability**
21
22 67 • **Benefit and function**
23
24
25 68 • **Landscape**
26
27 69 • **Humanities and culture preservation)**
28
29
30 70 • **Creativity**
31

32 71 Table 1 illustrates the evaluation items for each key indicator.
33
34

57 58 59 60 61 62 63 64 65	Creativity	<ul style="list-style-type: none"> • <u>Introduction of new materials, new construction methods, new technologies, etc.</u> • <u>Innovation in engineering project design</u>

- **Establishment of incentives mechanism to encourage innovation**
- Application of value engineering

73 In table 1, the underlined, with the bold font items, which are well performed in the ALRMS
74 project.

75 3. Project description

76 The Ankeng Light Rail Metro System (ALRMS) is a Design-Build (DB) based contract
77 project, which is located in Hsindian District, New Taipei City, Taiwan. The ALRMS project was
78 started in 2016, and estimated to serve for transportation service in 2022. The client of the ALRMS
79 is the Department of Rapid Transit Systems (DRTS), New Taipei City Government. The main
80 Contractor of ALRMS is New Asia Construction and Development Corporation (NA), which
81 includes the detailed design and construction stages. The ALRMS has a total length of 7.5
82 kilometers, and it contains nine stations, K1 to K9, including five elevated stations (K2, K6 to K9)
83 and four at-grade stations (K1, K3 to K5). The route of the ALRMS started with a depot yard near
84 to the Antai Road and ended in the Shisizhang station to connect to the MRT Cycle Line. Figure 2
85 shows the route layout of the ALRMS project.

86 There are three prime bridges, which crossing the Hsiapei Highway, No.3 Free Way, and the
87 Hsindian River, respectively. The Anhsin Bridge (AB) is the one to cross the Hsindian River and
88 it is one of the major parts of ALRMS, and serves as the most critical transportation route to connect
89 two banks of the Hsindian River, Ankeng and Hsindian districts.

90 In the design stage, all of the sustainability issues mentioned above were taken into
91 consideration to determine the bridge structure type. The engineers evaluated all key indicators
92 with the evaluation items to select the most sustainable option for detailed design and site
93 construction.

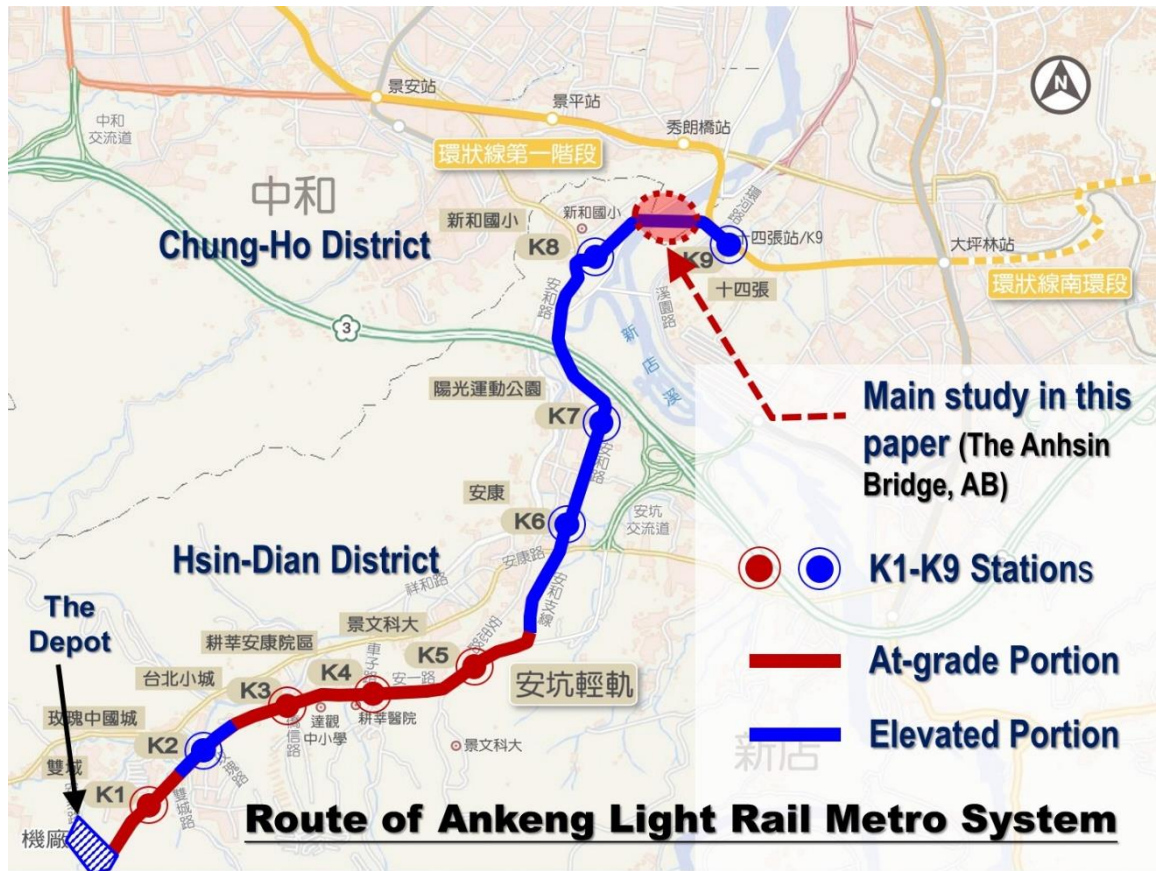

Figure 2: The route layout of the Ankeng Light Rail Metro System (ALRMS).

In figure 2, the marked pink area is the location of AB in the ALRMS route. It connects the two banks of the Hsindian River, between the K8 and K9 stations.

The engineers focus on the sustainability achievements that might be reached for selecting the options of the structure type for the AB. The AB structure frame's final determination is designed to be an asymmetry cable-stayed design with truss frames (ABCSTF). A total of 12 pairs of steel cables are installed between the steel pier column and the top steel box beam of the truss frame. Four different numbers of tendons, 55, 61, 66, and 73, are contained in different pairs of cables depending on the analyzed necessary prestressing-force.

In this paper, the authors would like to share their experiences on the option decision and the followed sustainability practices of the AB in the ALRMS project.

1
2
3 106 **4. The evaluation and determination for the Bridge structure type**

4
5
6 107 When developing the Anhsin Bridge (AB) construction for the ALRMS project, the original
7
8 108 concept from the client, DRTS, was to design AB as a “steel arch” bridge (SAB). Figure 3 shows
9
10 109 the original idea of the design and construction for the Abhsin Bridge [6].
11

57 110
58 111 **Figure 3:** The original idea of the design and construction for the Abhsin Bridge [6]
59

60 112 This option is indicated in the basic design concept of the Contract documents provided by the
61 113 client, DRTS. The construction of the steel arch bridge would inevitably require the setting of some
62 114 piers to be located in the Hsindian River reservation zone. As shown in Figure 3, the temporary
63 115 shoring truss needed to be installed in the reservation zone to support the members of the steel arch
64 116 frame. Also, the temporary access steel bridge is necessary to use the construction equipment.
65 117 Under this condition, the steel materials would be used in a massive quantity, and the total duration
66 118 will be significantly enlarged. In addition, the risk of construction work might be substantially
67 119 increased during the erection of steel columns. To minimize the possibility of danger, engineers
68 120 made their efforts to prevent the pier from being located in the flow area. All these construction
69 121 methods would pose a harmful situation for the river flow. It might also impact the environment
70 122 and ecological condition of the Hsiindian River.
71

72 123 Furthermore, Taiwan is a high typhoon-frequent area during the summer season; all the
73 124 construction machines and equipment will be hazardous whenever the typhoon attack the
74
75

1
2
3 125 construction site. The equipment would be faced a high-risk condition to stay in the access steel
4
5 126 bridge during the frequent typhoon season. Thus, the Contractor NA proposed an alternative
6
7 127 method with new, safer structure type, the ABCSTF, which instead of the original steel arch frame
8
9 128 for this prime bridge of the ALRMS. Figure 4 shows the draft sketch and simulation image of the
10
11
12
13 129 new AB.

130
131 **Figure 4:** The draft sketch and simulation image of the new AB [6]

132
133 When selecting the structure type of the AB, based on the sustainability key indicators listed in
134 Table 1, the engineers compare the performances between the SAB and the ABCSTF to provide
135 sufficient information for the decision-maker's final determination. Table 2 lists the evaluated
136 performances for SAB and ABCSTF. The operation/maintenance stage, as well as the construction
137 stage, are covered in the evaluation of these two options. From the lifecycle of the bridge, to reduce
the harmful impact to the environment protection and ecological conservation in the construction

stage represent the equivalent importance with the operation/maintenance stage.

Table 2: The evaluated performances for SAB and ABCSTF, based on sustainability key indicators.

Key indicators	Original planning: The steel arch bridge (SAB)	Alternative option: The asymmetry cable-stayed design with truss frames (ABCSTF)
Safety and risk mitigation		●
Reliability	●	●
Environment protection		●
Ecological conservation		●
Durability	●	●
Landscape		●
Construction Duration		●
Creativity		●
Final determination		●

Table 2 shows that the Contractor (NA) obtained the comparison results based on the sustainability key indicators, and made the final determination to select the ABCSTF as the structure type of the Anhsin Bridge (AB).

5. Sustainability Practices in Anhsin Bridge (AB)

Most of the sustainability issues are well-discussed and performed in the ALRMS project. Since the AB is a part of the entire project, it focuses on some critical items of the sustainability key indicators, including Risk Mitigation and Reliability, Environmental Protection, Ecology, Durability, Landscape, and Creativity.

5.1 Risk Mitigation and Reliability

The safety of infrastructure is always the top priority of consideration. Verification and enhancement of safety management during the lifecycle are essential to the engineers. The alternated structure type of AB includes three major parts, which are the 130m height steel pylon,

1
2
3 153 the 502m steel truss frame, and the 1,250 tons of steel cables, respectively. Even though the
4
5 154 engineers determine to use the ABCSTF structure type for the AB, however, every parts'
6
7 155 construction might lead to the happiness of danger. Therefore, the risk mitigation work is the
8
9 156 essential responsibility of the engineers to prevent such a risk possibility. To resolve and decrease
10
11 157 the risk possibility, some unique-designed reliable construction facilities and equipment were
12
13 158 proposed in the construction of AB, including the heave duty tower crane, and the erection system
14
15 159 for truss frame (ESTF).

160 5.1.1 Erection for steel pylon and truss frame

161 A heavy-duty tower crane, ST3330, was installed for the erection of 17 segments of the steel
162 pylon. The tower crane was established near the steel pylon and fixed by four tie-in frame layers.
163 Figure 5 shows the tie-in members connecting to the mast tower members.

Figure 5: The photo of ST3330 tower crane

166 The assembly of tower crane and AB steel pylon, which are connected by the tie-in sets, can
167 reduce the influences of river flow during the typhoon season. The temporary working platform
168 was pre-installed to each pylon segment and lifted along with the segment erection. Figures 6 and
169 7 show the ST3330 tower crane photos and the inspection of the temporary working platform by the

32
33

171
172 **Figure 6:** The photo of ST3330 tower crane

173
174 **Figure 7:** The inspection of the temporary working platform by the corresponding author

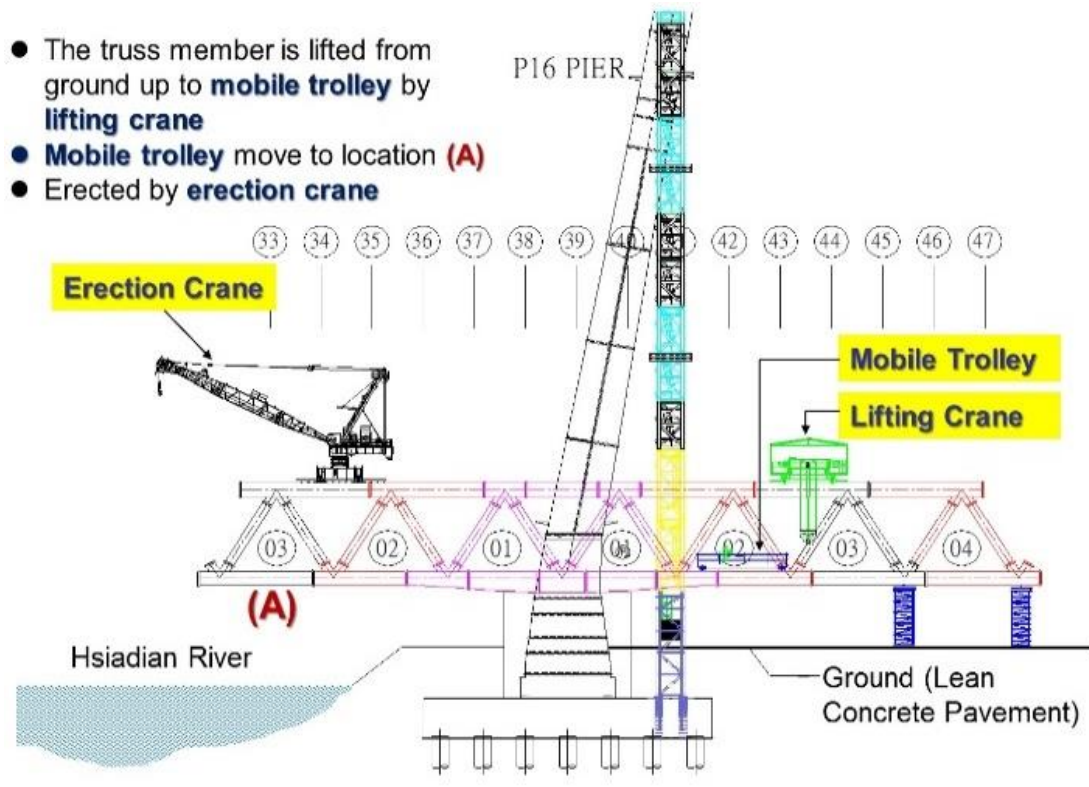

175 To avoid the river flow from being affected by the temporary shoring system during the erection
176 of the steel truss frame, the engineers proposed to use the erection system for the truss frame (ESTF)
177 for the erection work. Since the tower crane and other mobile cranes are not feasible for the erection

61
62
63
64
65

1
2
3 178 of all steel members, the ESTF shall provide the lifting, transporting, and erection function for the
4
5 179 construction of the steel truss frame. Thus, the ESTF is newly designed to serve as the construction
6
7 180 facility that contains some devices for the erection of the prominent horizontal steel truss members.
8
9
10 181 It included three major devices of heavy-duty equipment:

- 12 1. a **Lifting Crane** with a capacity of 48 tons
- 13 182
- 14 2. a **Mobile Trolley** that can handle the steel members up to 35 tons
- 15 183
- 16 3. an **Erection Crane** with a lifting ability of 50 tons
- 17 184

18 185 The ESTS is a specially designed equipment set to fit the site necessity of the steel truss frame
19
20
21
22 186 construction of AB [6]. Figure 8 shows the prime devices of the ESTF.

187
188 **Figure 8:** The design drawing of the erection system for the truss frame (ESTF) [6].

189 The lifting crane lifted the truss frame member onto the mobile trolley platform. The mobile
190 trolley then delivered the member, moved at a speed of six meters per minute, toward the erection
191 zone, refer to the location (A) of Figure 8. After the steel members arrived at the erection zone, the

1
2
3 192 erection crane took over all installation work. Figure 9 shows the installation steps of the steel truss
4
5 193 frame.

Installation Steps for the truss frame of Anhsin Bridge

31 194

32 195

Figure 9: The installation steps of the steel truss frame

33
34
35 196 By adopting ESTF, no temporary equipment or structure was needed in the river reservation zone
36
37 197 during the construction of the steel truss frame. It had significantly reduced the possibility of the
38
39 198 risk. Moreover, the overall construction duration is shortened due to the absence of the temporary
40
41 199 shoring system and the access steel bridge in the river reservation zone. Figures 10 and 11 show
42
43 200 the site photos of the ESTF and the bolt tightening of the steel truss frame under the corresponding
44
45 201 author's supervision, respectively [6].

We know that performing the proper safety management during the installation of steel cable could guarantee excellent quality for the bridge. The arrangement of cat way with safety guard and temporary stairs/ladders, which provided the safe environment for the installers when performing the steel cable installation work. Figure 12 shows the safety facilities for the installation work. Figure 13 shows the site photos of the safety facilities.

217 *5.2 Environmental Protection and Ecology*

218 Considering environmental sustainability, with the statements in the above sections, the
219 Contractor (NA) proposed the newly designed ABCSTF to be the structure frame type of the Anhsin
220 Bridge (AB). This well-designed structure frame, combined with the 12 pairs of steel cable,
221 achieves the most extended bridge span length of 225 m for the rail system in Taiwan. A

1
2
3 222 friendly environmental achievement was made by adopting ABCSTF. Besides, the impact on river
4
5 223 flow and species in the river was minimized in the construction and operation stages [12]. Also,
6
7 224 carbon emission was reduced through optimizing equipment and machine management [13]. This
8
9 225 achievement was realized especially due to the good planning of BSTF [6]. In addition, since
10
11 226 construction could severely impact the habitats of local species, biologists were engaged in the AB
12
13 227 project, and they implemented a research program for Hsindian River and its tributaries to monitor
14
15 228 any changes in species' population and health during construction [6]. Figure 14 shows some
16
17 229 species that were monitored, observed, and analyzed [12]. Besides, the cleanup work for the
18
19 230 Hsindian River's siltation was periodically performed for the smooth river flow. Monitoring for
20
21 231 the quality of river quality was also executed regularly to verify the influence of the water caused by
22
23 232 the AB construction work.

5.3 Durability

5.3.1 Huge load on pier foundation: design, construction, and inspection

The total length of AB is 502m, and it includes four piers, P9-15, P9-16, P9-17, and P9-18, are

1
2
3 238 designed as the substructure of the bridge. There are three spans on these four piers with a span
4
5 239 length of 225m, 150m, and 127m, respectively, as shown in Figure 4. Due to the long span length
6
7 240 (225m) of the Anhsin Bridge by adopting ABCSTF, no pier is necessary to be built in the Hsindian
8
9 241 River flow zone. Therefore, most of the Anhsin Bridge's load, including the pylon, steel truss frame,
10
11 242 and the life load by the trains, will apply to pier No. P9-16. Thus, the loading capacity of the P9-
12
13 243 16 should be sufficient to bear the extremely huge loads. The live and dead loads of the 375m truss
14
15 244 frame are transferred to the pylon of the P9-16 pier by the 24 steel cables. Undoubtedly, most of
16
17 245 the bridge loads should be taken by the P9-16 pier, and a large load capacity is required for the P9-
18
19 246 16 pier and the piles. [6].

20
21
22
23
24
25 247 The foundation of P9-16 is designed to be laid on a 5.5m thickness foundation, which is
26
27 248 supported by 42 pieces of 2m-diameter, 35m-depth borehole piles. For the success of the P9-16
28
29 249 and other piers' construction, a well-prepared construction working plan [14], as well as the strict on-
30
31 250 site quality control (QC) procedures for the piles and pile-cap [15], would be the best guarantee for
32
33 251 the durability of the bridge [6]. According to the working and QC procedures, a qualified QC
34
35 252 team was established to conduct the strict inspection and test. All tests and inspection results
36
37 253 represented a high quality of the constructed piles and the pile-cap. Figure 15 shows the
38
39 254 construction of the piles supervised by the corresponding author, and Figure 16 shows the inspection
40

260 5.3.2 Pile static loading test

261 Since the extremely massive loads will be applied to the P9-16 pier, the verification of the pile
 262 capacity is essentially necessary before the construction of P9-16 foundation. The bearing capacity
 263 of the test pile and the friction of the anchor pile were calculated using Eqs. (1) as follows:

264
$$Q_u = q_b A_b + \sum f_s A_s \quad (1)$$

65

1
2
3 265 Where:

4
5 266 Q_u : The total bearing capacity of the pile.

6
7
8 267 q_b : The bearing stress of the soil in the pile tip zone.

9
10 268 A_b : The section area of the pile tip.

11
12 269 f_s : The friction stress between the pile's side surface and the soil.

13
14
15 270 A_s : The area of the pile's side surface.

16
17 271 Figure 17 shows the principle of Eq.(1).

272

273 **Figure 17:** The principle of Eq.(1): $Q_u = q_b A_b + \sum f_s A_s$

274 Besides, the total bearing capacity of the piles can also be calculated from the Eq.(2) as follows:

275
$$Q_s = (N_s/3) * 2\pi * A_s \quad (2)$$

276 Where:

277 N_s : N-value of soil obtained from the standard penetration test (SPT).

278 A_s : The area of the pile's side surface.

279 In this case, the total bearing capacity of the test and anchor piles are specified by the larger value

280 of the Q_u and Q_s . It also defined the detailed design for the pile diameter and the length of the piles

281 for the P9-16 foundation/pile cap. The followed processes are to verify the capacity of the pile

could meet the designed requirement. The engineers established a detailed test procedure to verify the actual performance of the piles [16]. Table 3 shows the specified data for the pile test [6].

Table 3: Basic data for the pile test [6, 14].

items	Unit	Values
Design pile length	m	35.0
Diameter of the test pile	cm	200
Extended portion length	m	12.5
Total pile length (includeing extended portion)	m	35.0+12.5=47.5 m
Design vertical load (under normal condition)	Tons	974
Design vertical load (under earth quake condition)	Tons	2,287
Friction of extended portion	Tons	593.96
Maximum test load	Tons	2,881 t
Anchor force type		Anchor piles
Anchor force supply		4 anchor piles, Diameter =2.0m , L=47.2m
Connection rebars		SD420W#11-24×2=48 Pics.
Rebar welding		Fillet weld, L=16cm

Based on the Table 3, the maximum test load is calculated using Eq. (3) as follows:

$$\text{Max.}\{(2* \text{Normal vertical load}), \text{Earthquake vertical load}\}+ \text{Friction of extended portion} \quad (3)$$

According to Eq.(3), the maximum test load was calculated as:

$$\text{Maximum test load} = (2,287+593.96) = \mathbf{2,880.96}, \text{ namely } \mathbf{2,881} \text{ tons.}$$

There are two options for applying the test load: the concrete mass blocks and the hydraulic jack sets. In this case, the engineer selected the hydraulic jack sets due to the extremely massive load needed to be provided for the test. Eight pieces of 500 tons hydraulic jacks were assembled to provide sufficient forces for the static loading test. Figure 18 shows the assembly of the pile static loading test.

294

295

Figure 18: The assembly of the pile static loading test.

296

297

298

The testing equipment was set by the major components, including hydraulic jack sets, main and secondary anchor beams, reference beams, dial gauges, and monitoring instruments, as shown in Figure 18. Figure 19 shows the site photos of the test equipment.

299

300

301

Figure 19: The testing equipment: (a) the site test assembly, and (b) monitor instruments checked by the corresponding author.

302

According to the test procedure [16], the test pile was selected from the 42 permanent piles, and

the neighboring four piles served to provide the anchor force during the conducting of the static loading test. The main anchor beam and two secondary beams were the reflection members for the vertical load transferring, as shown in Figure 18. The vertical loads of 2,881 tons should be gradually applied using the hydraulic jack sets. Table 4 shows the pile test steps and the load applied in each stage [6, 16].

Table 4: The pile test steps and the load applied in each stage [6, 16].

Note	□ : Load increasing		■ : Load decreasing			▲ : Load release			

After eight hours of static loading test, the maximum load and the corresponding pile top settlement were 2,881 tons and 16.67mm, respectively. The load was gradually released down to zero after keeping of maximum load for 12 hours. During the load releasing stage, the pile top settlement was gradually re-expanded. The net settlement, 3.52mm, was measured immediately while the vertical load was released down to zero. Figure 20 shows the load-settlement diagram of the pile static loading test.

Figure 20: The load-settlement diagram of the pile static loading test [6].

The maximum settlement and net settlement verified that the actual pile capacity met the design requirement with a safety factor of 3. The test results indicated excellent and reliable durability for the lifecycle of the AB.

5.3.2 Wind force: wind tunnel test

We are aware that the wind force might cause incredibly harmful damages to the bridge's structure. It had some bridge's collapse experiences, which were not sufficiently designed to bear the horizontal wind force, especially from the Tacoma Narrows Bridge collapse accident. In the Anhsin Bridge of ALRMS project, the wind force had been considered during the design stage. Furthermore, prior to the connection of the steel truss frame and Pier P9-15, the bridge body was not stable due to the cantilever condition. The horizontal force caused by wind, such as that from

1
2
3 327 typhoons, might seriously damage the structure of the steel truss frame. For the realization of the
4
5 328 lateral displacement of the steel truss frame under cantilever condition, wind tunnel tests [17] were
6
7
8 329 conducted.

9
10 330 The bridge members were produced by 3-D printing on a 1/100 scale. A series of tests in
11
12 331 different wind directions, including 30°, 45°, 60°, 90°, 120°, 135° and 150°, were conducted. The
13
14
15 332 maximum lateral displacement under the most critical condition was measured as 830mm with a
16
17 333 74m/second wind speed. The maximum wind force was calculated using Eq. (4).

18
19
20
21 334
$$P = 0.124 * V^2$$
 (4)
22

23
24 335 Through careful analysis of the steel truss frame with a lateral displacement of 830mm, the bridge
25
26 336 structure was confirmed to be safe with a reliable safety factor. Figure 21 shows the wind tunnel
27
28
29 337 test in the laboratory [6, 17].

339 **Figure 21:** The wind tunnel test in the laboratory [6, 17].

340 5.3.3 Management of massive member sizes

341 More than fifty thousand steel members of various shapes and sizes were specified in the drawing.
342 A reliable management system for raw materials and their manufacturing, assembly, transportation,
343 and erection should be established in order to carry out construction work without any mistakes [6].

344 Figure 22 shows the traceability of material management.

345 Engineers establish the traceability of material and steel members management system for
346 numbering, batching, identification, and verification of the manufacture, transportation, and site
347 installation of the AB [18]. The functional management system's operation leads the construction
348 of AB to a successful performance.

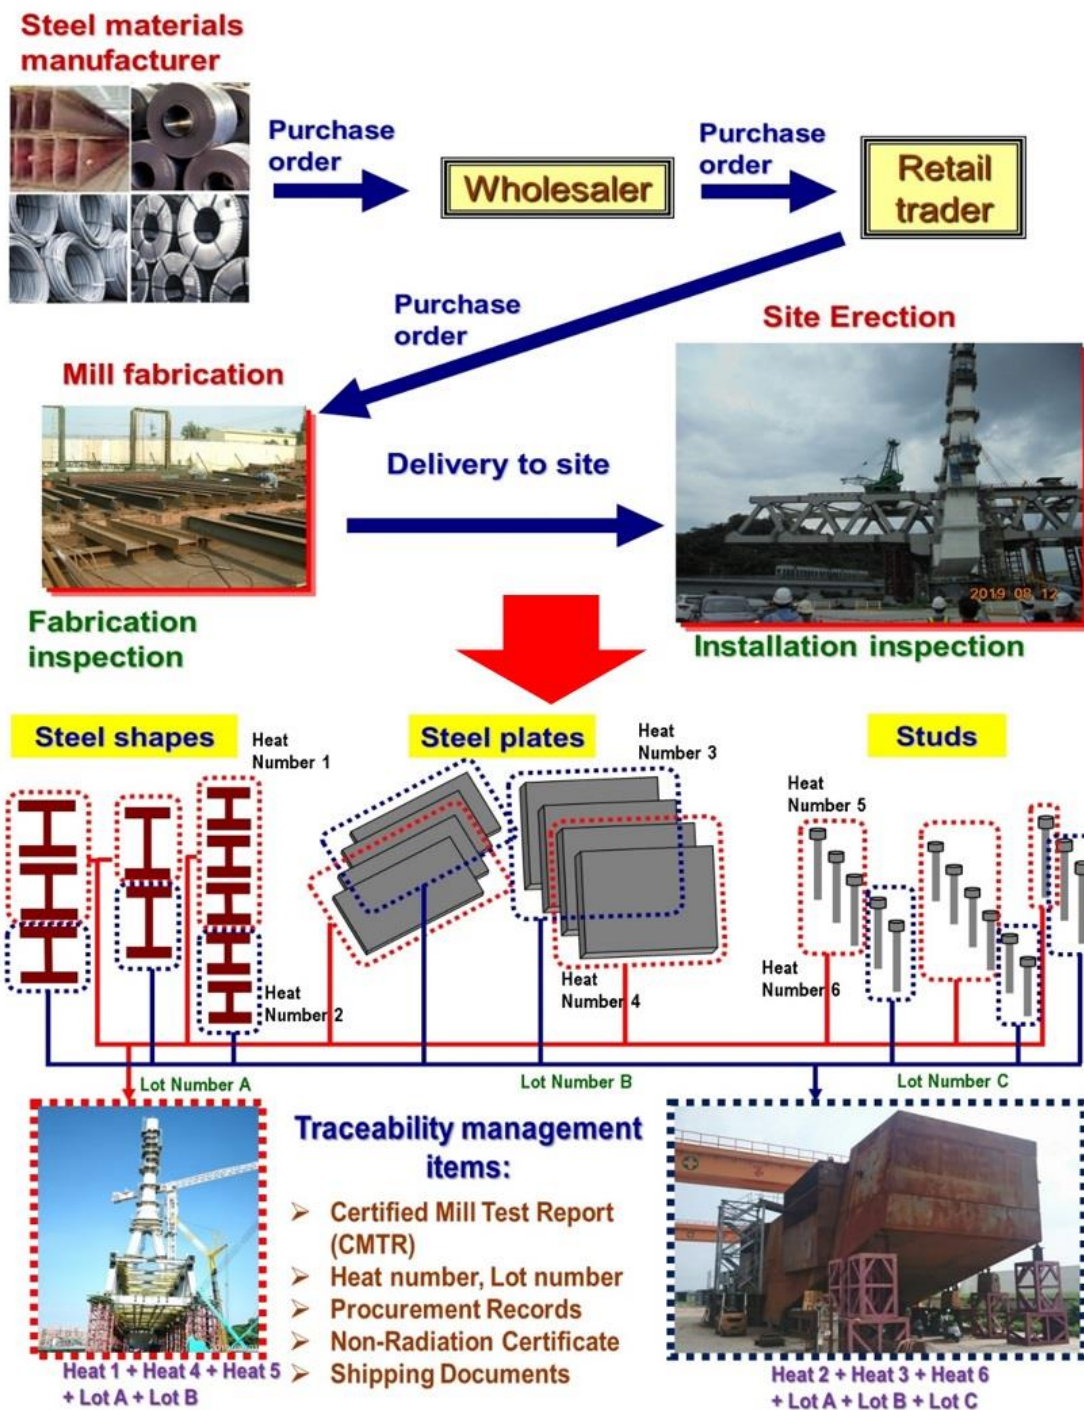

Figure 22: The traceability of material management.

5.3.4 Steel Cable system

The quality of steel cables represents the durability of the AB. Corrosion protection for the cables is the most critical issue of the quality assurance processes. Figure 23 illustrates the detailed

1
2
3 assembly and corrosion protection system for the steel cables. Figure 24 shows the tendon and

359 **Figure 24:** The (a) tendon, and (b) HDPE pipe inspected by the corresponding author.

360
361 *5.4 Landscape and Creativity*

362 When people watch the shape of the AB, combine the pylon with the cable-stayed system, it
363 could be imagined to be a high flying eagle. The outstanding landscape design represents the

60

32

33
34 368 Adopting building information modeling (BIM) [19] helped engineers with excellent
35
36 369 management for Anhsin Bridge (AB) construction. Every single piece could be modeled in 3-D
37
38 using BIM with traceable ID number, shape, size, installation location, etc. BIM not only enabled
39 370 engineers to manage construction work efficiently and effectively, but also detected potential clashes
40
41 371 between different members and resolved them prior to installation and/or erection [6]. Figure 26

376 **Conclusion**

377 The contractor proposed the asymmetry cable-stayed design with truss frame (ABCSTF) method
378 for the Anhsin Bridge construction to meet the goal of sustainability achievements, including Risk
379 Mitigation and Reliability, Environmental Protection, Ecology, Durability, Landscape, and Creativity.
380 Besides, the application of BIM technique helped engineers to play their talents and creativities for
381 the bridge design. Moreover, the outstanding landscape design had accomplished the
382 accomplishments of humanity. The presented successful practices adopted in this project for
383 sustainability issues during the design, construction, and operation stages, could serve as a useful
384 reference for similar bridge projects in the future.
